Programming in C/C++

UNIT-I

C language: Introduction; Tokens; Keywords; Identifier; Variables; Constants; Operators; Expression; Data types; Operator precedence

Statement: Input statement, Output statement, Conditional and Unconditional Control Statement – Looping Statement: while, do-while, for – nested loop – Arrays.

Overview of C++: Object oriented programming, Introducing C++ classes, Concepts of object oriented programming. Classes & Objects: Classes, Structure & classes, Union & Classes, Friend function, Friend classes, Inline function, Scope resolution operator, Static class members: Static data member, Static member function, Passing objects to function, Returning objects, Object assignment.

UNIT-II

Array and Pointers references: Array of objects, Pointers to object, Type checking C++ pointers, The This pointer, Pointer to derived types, Pointer to class members, References: Reference parameter, Passing references to objects, Returning reference, Independent reference, C++ 's dynamic allocation operators, Initializing allocated memory, Allocating Array, Allocating objects.

Constructor & Destructor: Introduction, Constructor, Parameterized constructor, Multiple constructor in a class, Constructor with default argument, Copy constructor, Default Argument, Constructing two dimensional Array, Destructor.

UNIT-III

Function & operator overloading: Function overloading, Overloading constructor function finding the address of an overloaded function, Operator Overloading: Creating a member operator function, Creating Prefix & Postfix forms of the increment & decrement operation, Overloading the shorthand operation (i.e. +=,-= etc), Operator overloading restrictions, Operator overloading using friend function, Overloading New & Delete, Overloading some special operators, Overloading [], (), -, comma operator, Overloading <<.

UNIT-IV

Inheritance: Base class Access control, Inheritance & protected members, Protected base class inheritance, Inheriting multiple base classes, Constructors, destructors & Inheritance, When constructor & destructor function are executed, Passing parameters to base class constructors, Granting access. Virtual functions & Polymorphism: Virtual base classes; Virtual function, Pure Virtual functions, early Vs. late binding

UNIT-V

String Handling: String declaration; String library functions; String Manipulation; Creating string objects, manipulating string objects, relational operators, string characteristics, Comparing and swapping Sorting: Bubble sort, Selection sort, Insertion sort

Searching: Linear search, Binary search

What is C?

C is a general-purpose programming language created by Dennis Ritchie at the Bell Laboratories in 1972.

It is a very popular language, despite being old.

C is strongly associated with UNIX, as it was developed to write the UNIX operating system.

Why Learn C?

It is one of the most popular programming language in the world

If you know C, you will have no problem learning other popular programming languages such as Java, Python,

C++, C#, etc, as the syntax is similar

C is very fast, compared to other programming languages, like Java and Python

C is very versatile; it can be used in both applications and technologies

Similarities between C and C++ are:

Both the languages have a similar syntax.

Code structure of both the languages are same.

The compilation of both the languages is similar.

They share the same basic syntax. Nearly all of C's operators and keywords are also present in C++ and do the same thing.

C++ has a slightly extended grammar than C, but the basic grammar is the same.

Basic memory model of both is very close to the hardware.

Same notions of stack, heap, file-scope and static variables are present in both the languages.

C	C++
C was developed by Dennis Ritchie between the year 1969 and 1973 at AT&T Bell Labs.	C++ was developed by Bjarne Stroustrup in 1979.
C does no support polymorphism, encapsulation, and inheritance which means that C does not support object oriented programming.	C++ supports <u>polymorphism</u> , <u>encapsulation</u> , and <u>inheritance</u> because it is an object oriented programming language.
C is a subset of C++.	C++ is a superset of C.
C contains 32 <u>keywords</u> .	C++ contains 63 <u>keywords</u> .
For the development of code, C supports <u>procedural</u> <u>programming</u> .	C++ is known as hybrid language because C++ supports both <u>procedural</u> and <u>object oriented programming paradigms</u> .
Data and functions are separated in C because it is a procedural programming language.	Data and functions are encapsulated together in form of an object in C++

C	C++
C does not support information hiding.	Data is hidden by the Encapsulation to ensure that data structures and operators are used as intended.
Built-in data types is supported in C.	Built-in & user-defined data types is supported in C++.
C is a function driven language because C is a procedural programming language.	C++ is an object driven language because it is an object oriented programming.
Function and operator overloading is not supported in C.	Function and operator overloading is supported by C++.
C is a function-driven language.	C++ is an object-driven language
Functions in C are not defined inside structures.	Functions can be used inside a structure in C++.
Namespace features are not present inside the C.	Namespace is used by C++, which avoid name collisions.
Header file used by C is <u>stdio.h</u> .	Header file used by C++ is <u>iostream.h</u> .
Reference variables are not supported by C.	Reference variables are supported by C++.
Virtual and friend functions are not supported by C.	<u>Virtual</u> and <u>friend functions</u> are supported by C++.
C does not support inheritance.	C++ supports inheritance.

Applications of C Programming

C was initially used for system development work, particularly the programs that make-up the operating system. C was adopted as a system development language because it produces code that runs nearly as fast as the code written in assembly language. Some examples of the use of C are -

A C program basically consists of the following parts –

Preprocessor Commands
Functions
Variables
Statements & Expressions
Comments

Let us look at a simple code that would print the words "Hello World" –

#include <stdio.h>

int main() {
 /* my first program in C */
 printf("Hello, World! \n");

return 0;

C++ Program

Before starting the abcd of C++ language, we need to learn how to write, compile and run the first C++ program.

To write the first C++ program, open the C++ console and write the following code:

```
#include <iostream.h> includes the standard input output library functions. It provides cin and cout methods for reading from input and writing to output respectively.

void main() {
    clrscr();
    cout << "Welcome to C++ Programming.";
    getch();
}

#include <iostream.h> includes the standard input output library functions. It provides cin and cout methods for reading from input and writing to output respectively.

#include <conio.h> includes the console input output library functions. The getch() function is defined in conio.h file.
```

void main() The main() function is the entry point of every program in C++ language. The void keyword specifies that it returns no value.

cout << "Welcome to C++ Programming." is used to print the data "Welcome to C++ Programming." on the console.

getch() The getch() function asks for a single character. Until you press any key, it blocks the screen.

How to compile and run the C++ program

There are 2 ways to compile and run the C++ program, by menu and by shortcut.

By menu

Now **click on the compile menu then compile sub menu** to compile the c++ program.

Then **click on the run menu then run sub menu** to run the c++ program.

By shortcut

Or, press ctrl+f9 keys compile and run the program directly. You will see the following output on user screen.

we can view the user screen any time by pressing the alt+f5 keys.

Now **press Esc** to return to the turbo c++ console.

C++ Basic Input/Output

C++ I/O operation is using the stream concept. Stream is the sequence of bytes or flow of data. It makes the performance fast.

If bytes flow from main memory to device like printer, display screen, or a network connection, etc, this is called as **output operation**.

If bytes flow from device like printer, display screen, or a network connection, etc to main memory, this is called as **input operation**.

I/O Library Header Files

Let us see the common header files used in C++ programming

are

Header File Function and Description

<iostream> It is used to define the cout, cin and cerr objects, which correspond to standard output stream, standard input stream and standard error stream, respectively.

<iomanip> It is used to declare services useful for performing formatted I/O, such as setprecision and setw.

<fstream> It is used to declare services for user-controlled file processing.

Standard output stream (cout)

The **cout** is a predefined object of **ostream** class. It is connected with the standard output device, which is usually a display screen. The cout is used in conjunction with stream insertion operator (<<) to display the output on a console

Let's see the simple example of standard output stream (cout):

```
include <iostream>
using namespace std;
int main() {
  char ary[] = "Welcome to C++ tutorial";
  cout << "Value of ary is: " << ary << endl;
}</pre>
```

Standard input stream (cin)

The cin is a predefined object of istream class. It is connected with the standard input device, which is usually a keyboard. The cin is used in conjunction with stream extraction operator (>>) to read the input from a console.

Let's see the simple example of standard input stream (cin):

```
#include <iostream.h>
int main() {
 int age;
 cout << "Enter your age: ";</pre>
 cin >> age;
 cout << "Your age is: " << age << endl;</pre>
    #include <iostream.h>
    int main() {
    cout << "C++ Tutorial";</pre>
    cout << " Javatpoint"<<endl;</pre>
    cout << "End of line"<<endl;</pre>
```

Standard end line (endl)

The endl is a predefined object of ostream class. It is used to insert a new line characters and flushes the stream.

Let's see the simple example of standard end line (endl):

C++ Variable

A variable is a name of memory location. It is used to store data. Its value can be changed and it can be reused many times.

It is a way to represent memory location through symbol so that it can be easily identified.

Let's see the syntax to declare a variable:

type variable_list;

int x; float y; char z; Here, x, y, z are variables and int, float, char are data types.

We can also provide values while declaring the variables as given below:

int x=5,b=10; //declaring 2 variable of integer type float f=30.8; char c='A';

Rules for defining variables

A variable can have alphabets, digits and underscore.

A variable name can start with alphabet and underscore only. It can't start with digit.

No white space is allowed within variable name.

A variable name must not be any reserved word or keyword e.g. char, float etc.

Valid variable names:

Invalid variable names:

int a;

int _ab;

int 4;

int x y;

int double;

C++ Data Types

A data type specifies the type of data that a variable can store such as integer, floating, character etc.

There are 4 types of data types in C++ language.

Types Data Types

Basic Data Type int, char, float, double, etc

Derived Data Type array, pointer, etc

Enumeration Data Type enum

User Defined Data Type structure

Basic Data Types

The basic data types are integer-based and floating-point based. C++ language supports both signed and unsigned literals.

The memory size of basic data types may change according to 32 or 64 bit operating system.

C++ Keywords

A keyword is a reserved word. You cannot use it as a variable name, constant name etc. A list of 32 Keywords in C++ Language which are also available in C language are given below.

auto	break default	case do	char	const	continue	
double	_	enum	extern	float	for	goto
int	long sizeof	register static	return	short	signed	
struct	switch volatile	typedef while	union	unsigned	void	

C++ Operators

An operator is simply a symbol that is used to perform operations. There can be many types of operations like arithmetic, logical, bitwise etc.

There are following types of operators to perform different types of operations in C language.

Arithmetic Operators
Relational Operators
Logical Operators
Bitwise Operators
Assignment Operator
Unary operator
Ternary or Conditional Operator
Misc Operator

Operator

Type

Arithmetic Operators

<,<=, >, >=, ==, !=

Unary Operator

Unary Operator

Ternary Operator

Ternary or Conditional Operator

C++ Identifiers

C++ identifiers in a program are used to refer to the name of the variables, functions, arrays, or other user-defined data types created by the programmer. They are the basic requirement of any language. Every language has its own rules for naming the identifiers.

In short, we can say that the C++ identifiers represent the essential elements in a program which are given below:

Constants

Variables

Functions

Labels

Defined data types

Some naming rules are common in both C and C++. They are as follows:

- 1. Only alphabetic characters, digits, and underscores are allowed.
- 2. The identifier name cannot start with a digit, i.e., the first letter should be alphabetical. After the first letter, we can use letters, digits, or underscores.
- 3. In C++, uppercase and lowercase letters are distinct. Therefore, we can say that C++ identifiers are case-sensitive.
- 4. A declared keyword cannot be used as a variable name.

For example, suppose we have two identifiers, named as 'FirstName', and 'Firstname'. Both the identifiers will be different as the letter 'N' in the first case in uppercase while lowercase in second. Therefore, it proves that identifiers are case-sensitive.

Valid Identifiers

The following are the examples of valid identifiers are:

```
Result
Test2
_sum
power
Invalid Identifiers
The following are the examples of invalid identifiers:
Sum-1 // containing special character '-'.
2data // the first letter is a digit.
break // use of a keyword
```

Let's look at a simple example to understand the concept of identifiers.

```
#include <iostream.h>

int main()
{
    int a;
    int A;
    cout<<"Enter the values of 'a' and 'A'";
    cin>>a;
    cin>>A;
    cout<<"\nThe values that you have entered are : "<<a<" , "<<A;
    return 0;
}</pre>
```

In the above code, we declare two variables 'a' and 'A'. Both the letters are same but they will behave as different identifiers. As we know that the identifiers are the casesensitive so both the identifiers will have different memory locations.

What are the keywords?

Keywords are the reserved words that have a special meaning to the compiler. They are reserved for a special purpose, which cannot be used as the identifiers. For example, 'for', 'break', 'while', 'if', 'else', etc. are the predefined words where predefined words are those words whose meaning is already known by the compiler. Whereas, the identifiers are the names which are defined by the programmer to the program elements such as variables, functions, arrays, objects, classes.

C++ if-else

In C++ programming, if statement is used to test the condition. There are various types of if statements in C++.

if statement if-else statement nested if statement if-else-if ladder

C++ if-else

In C++ programming, if statement is used to test the condition. There are various types of if statements in C++.

if statement if-else statement nested if statement if-else-if ladder

```
C++ IF Statement
The C++ if statement tests the condition. It is executed if condition is true.
```

```
if(condition){
//code to be executed
}
```

```
C++ If Example
#include <iostream.h>
int main () {
  int num = 10;
     if (num % 2 == 0)
     {
        cout<<"It is even number";
     }
  return 0;
}</pre>
```

C++ IF-else Statement

The C++ if-else statement also tests the condition. It executes if block if condition is true otherwise else block is executed.

```
if(condition){
//code if condition is true
}else{
//code if condition is false
}
```

```
C++ If-else Example
#include <iostream.h>
int main () {
 int num = 11;
      if (num % 2 == 0)
         cout<<"It is even number";</pre>
       else
         cout<<"It is odd number";
 return 0;
```

```
C++ If-else Example: with input from user
#include <iostream>
int main () {
  int num;
  cout<<"Enter a Number: ";
  cin>>num;
      if (num % 2 == 0)
         cout<<"It is even number"<<endl;</pre>
       else
         cout<<"It is odd number"<<endl;
 return 0;
```

C++ IF-else-if ladder Statement The C++ if-else-if ladder statement executes one condition from multiple statements.

```
if(condition1){
//code to be executed if condition1 is true
}else if(condition2){
//code to be executed if condition2 is true
}
else if(condition3){
//code to be executed if condition3 is true
}
...
else{
//code to be executed if all the conditions are false
}
```

```
#include <iostream>
using namespace std;
int main () {
    int num;
   cout<<"Enter a number to check grade:";
   cin>>num;
      if (num <0 || num >100)
        cout<<"wrong number";
      else if(num >= 0 \&\& num < 50){
        cout<<"Fail";
      else if (num >= 50 \&\& num < 60)
        cout<<"D Grade";
      else if (num >= 60 \&\& num < 70)
        cout<<"C Grade";
      else if (num >= 70 && num < 80)
        cout<<"B Grade";
      else if (num >= 80 && num < 90)
        cout<<"A Grade";
      else if (num >= 90 && num <= 100)
        cout<<"A+ Grade";
```

```
C++ switch
```

The C++ switch statement executes one statement from multiple conditions. It is like if-else-if ladder statement in C++.

```
switch(expression){
                                                       #include <iostream>
case value1:
                                                       using namespace std;
//code to be executed;
                                                       int main () {
break;
                                                           int num;
case value2:
                                                           cout<<"Enter a number to check grade:";</pre>
//code to be executed;
                                                           cin>>num;
break;
                                                             switch (num)
. . . . . .
                                                               case 10: cout<<"It is 10"; break;
default:
                                                               case 20: cout<<"It is 20"; break;
//code to be executed if all cases are not matched;
                                                               case 30: cout<<"It is 30"; break;
break;
                                                               default: cout<<"Not 10, 20 or 30"; break;
```

C++ OOPs Concepts

The major purpose of C++ programming is to introduce the concept of object orientation to the C programming language.

Object Oriented Programming is a paradigm that provides many concepts such as inheritance, data binding, polymorphism etc.

The programming paradigm where everything is represented as an object is known as truly object-oriented programming language. Smalltalk is considered as the first truly object-oriented programming language.

OOPs (Object Oriented Programming System)

Object means a real word entity such as pen, chair, table etc. Object-Oriented Programming is a methodology or paradigm to design a program using classes and objects. It simplifies the software development and maintenance by providing some concepts:

Object

Any entity that has state and behavior is known as an object. For example: chair, pen, table, keyboard, bike etc. It can be physical and logical.

Class

Collection of objects is called class. It is a logical entity.

Inheritance

When one object acquires all the properties and behaviours of parent object i.e. known as inheritance. It provides code reusability. It is used to achieve runtime polymorphism.

Polymorphism

When one task is performed by different ways i.e. known as polymorphism. For example: to convince the customer differently, to draw something e.g. shape or rectangle etc.

In C++, we use Function overloading and Function overriding to achieve polymorphism.

Abstraction

Hiding internal details and showing functionality is known as abstraction. For example: phone call, we don't know the internal processing.

In C++, we use abstract class and interface to achieve abstraction.

Encapsulation

Binding (or wrapping) code and data together into a single unit is known as encapsulation. For example: capsule, it is wrapped with different medicines.

C++ Object and Class Example

```
#include <iostream.h>

class Student {
   public:
     int id;//data member (also instance variable)
     string name;//data member(also instance variable)
};
int main() {
   Student s1; //creating an object of Student
   s1.id = 201;
   s1.name = "Mtech";
   cout<<s1.id<<endl;
   cout<<s1.name<<endl;
   return 0;
}</pre>
```

C++ Class Example: Initialize and Display data through method

```
#include <iostream>
using namespace std;
class Student {
  public:
    int id;//data member (also instance variable)
    string name;//data member(also instance variable)
    void insert(int i, string n)
      id = i;
      name = n;
    void display()
      cout<<id<<" "<<name<<endl;
int main(void) {
  Student s1; //creating an object of Student
  Student s2; //creating an object of Student
  s1.insert(201, "Mtech");
  s2.insert(202, "MSC");
  s1.display();
  s2.display();
  return 0;
```
